

Network Security Review

goals:

- understand principles of network security:
 - cryptography and its *many* uses beyond "confidentiality"
 - authentication
 - message integrity
- security in practice:
 - firewalls and intrusion detection systems
 - security in application, transport, network, link layers

What is network security?

Confidentiality: only sender, intended receiver should “understand” message contents

- sender encrypts message
- receiver decrypts message

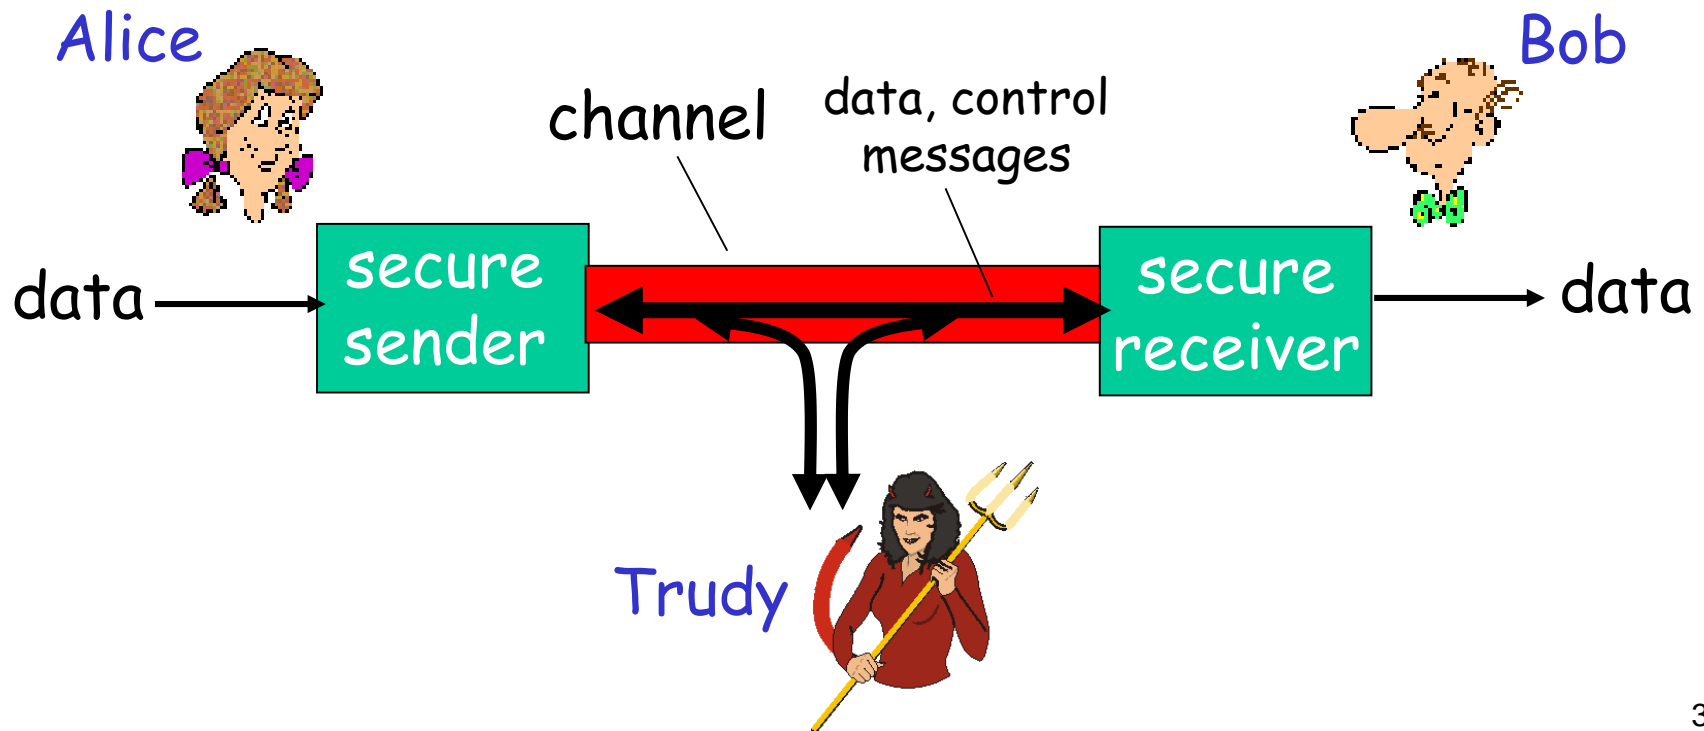

Authentication: sender, receiver want to confirm identity of each other

Message integrity: sender, receiver want to ensure message not altered (in transit, or afterwards) without detection

Access and availability: services must be accessible and available to users

Friends and enemies: Alice, Bob, Trudy

- ❑ well-known in network security world
- ❑ Bob, Alice want to communicate "securely"
- ❑ Trudy (intruder) may intercept, delete, add messages

Who might Bob, Alice be?

- ❑ ... well, *real-life* Bobs and Alices!
- ❑ Web browser/server for electronic transactions (e.g., on-line purchases)
- ❑ on-line banking client/server
- ❑ DNS servers
- ❑ routers exchanging routing table updates
- ❑ other examples?

There are bad guys (and girls) out there!

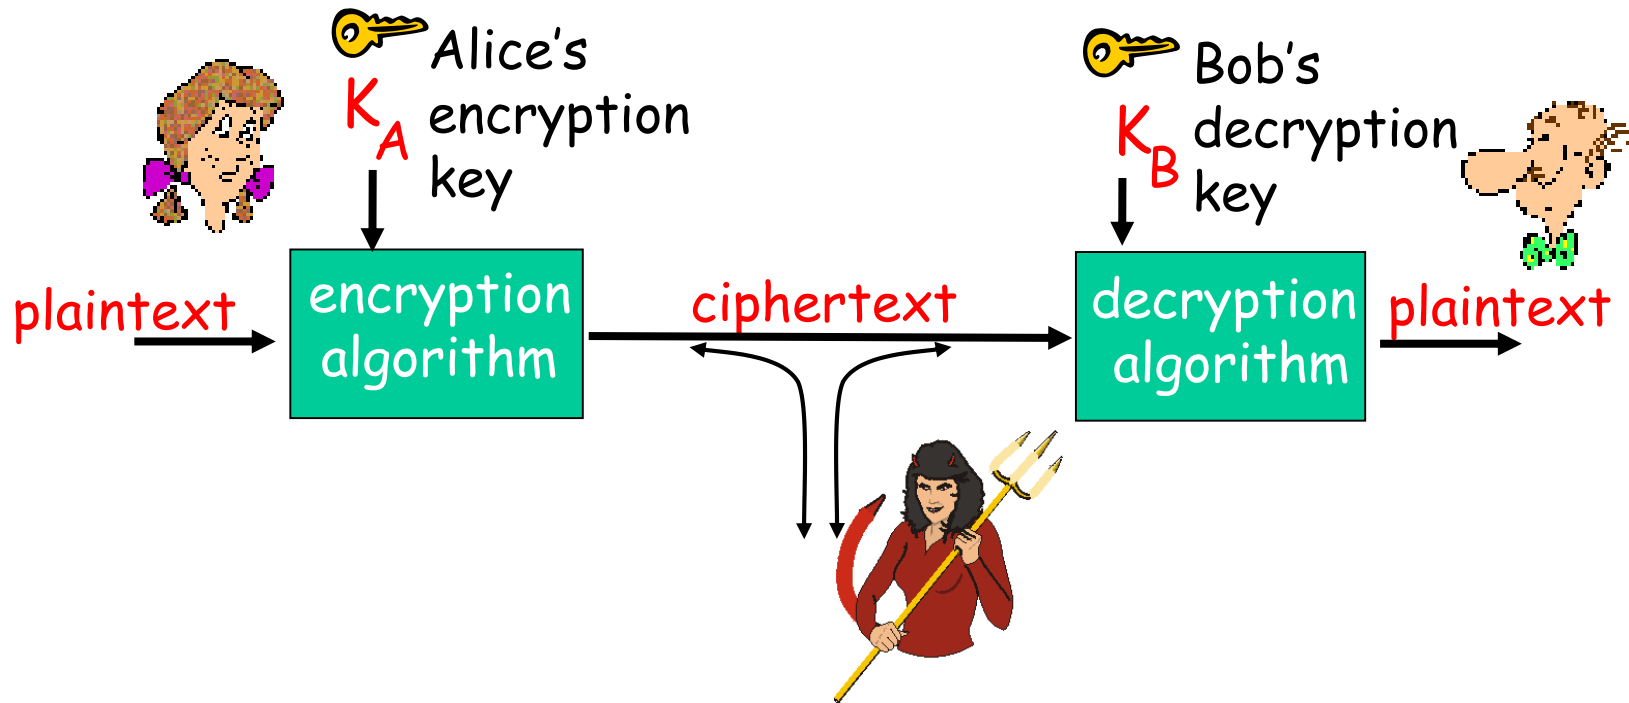

Q: What can a “bad guy” do?

A: a lot!

- *eavesdrop*: intercept messages
- actively *insert* messages into connection
- *impersonation*: can fake (spoof) source address in packet (or any field in packet)
- *hijacking*: “take over” ongoing connection by removing sender or receiver, inserting himself in place
- *denial of service*: prevent service from being used by others (e.g., by overloading resources)

more on this later

The language of cryptography

symmetric key crypto: sender, receiver keys *identical*
public-key crypto: encryption key *public*, decryption key *secret* (private)

Symmetric key cryptography

substitution cipher: substituting one thing for another

- monoalphabetic cipher: substitute one letter for another

plaintext:	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t	u	v	w	x	y	z
ciphertext:	m	n	b	v	c	x	z	a	s	d	f	g	h	j	k	l	p	o	i	u	y	t	r	e	w	q

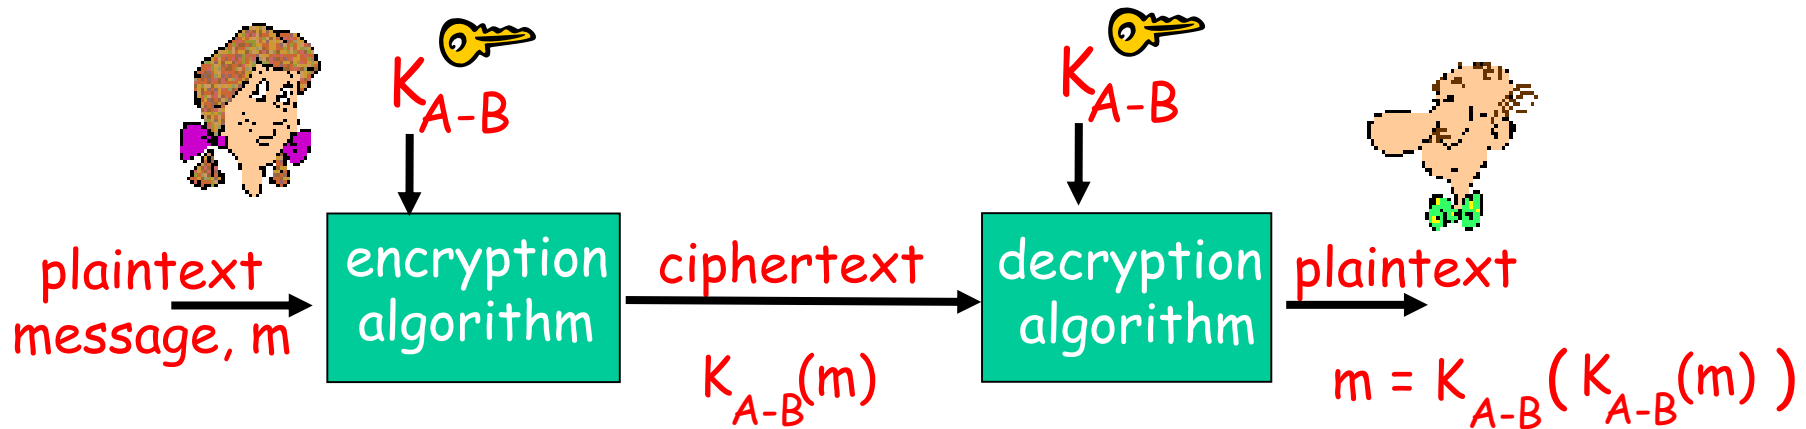

E.g.: Plaintext: bob. i love you. alice
ciphertext: nkn. s gktc wky. mgsbc

Q: How hard to break this simple cipher?:

- ☐ brute force (how hard?)
- ☐ other?

Symmetric key cryptography

symmetric key crypto: Bob and Alice share know same (symmetric) key: K_{A-B}

- e.g., key is knowing substitution pattern in mono alphabetic substitution cipher
- Q: how do Bob and Alice agree on key value?

Symmetric key crypto: DES

DES: Data Encryption Standard

- ❑ US encryption standard [NIST 1993]
- ❑ 56-bit symmetric key, 64-bit plaintext input
- ❑ block cipher with cipher block chaining
- ❑ how secure is DES?
 - DES Challenge: 56-bit-key-encrypted phrase decrypted (brute force) in less than a day
 - no known good analytic attack
- ❑ making DES more secure:
 - 3DES: encrypt 3 times with 3 different keys

Symmetric key crypto: DES

DES operation

initial permutation
16 identical “rounds”
of function
application, each
using different 48
bits of key
final permutation

AES: Advanced Encryption Standard

- ❑ new (Nov. 2001) symmetric-key NIST standard, replacing DES
- ❑ processes data in 128 bit blocks
- ❑ 128, 192, or 256 bit keys
- ❑ brute force decryption (try each key) taking 1 sec on DES, takes 149 trillion years for AES

Public key cryptography

symmetric key crypto

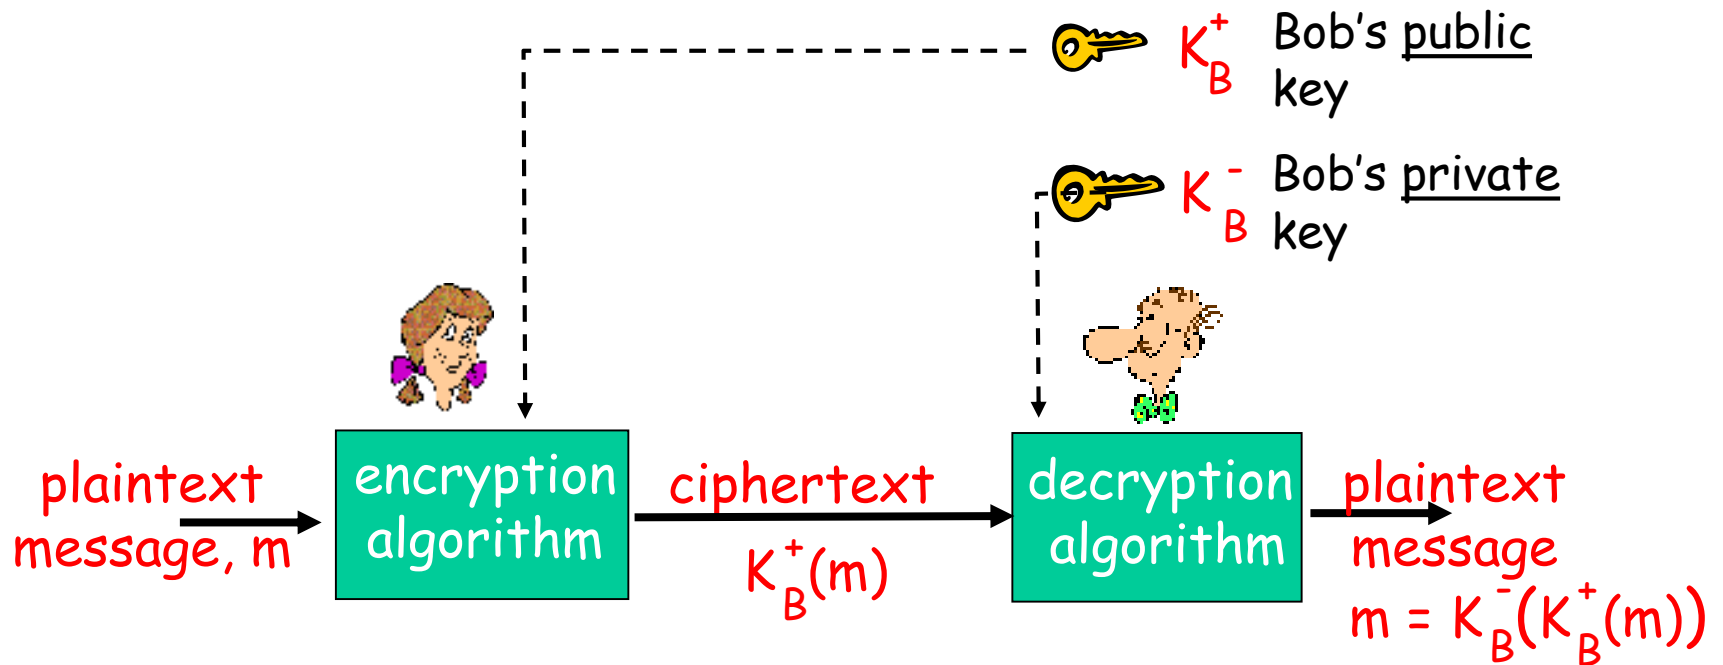

- ❑ requires sender, receiver know shared secret key
- ❑ Q: how to agree on key in first place (particularly if never "met")?

public key cryptography

- ❑ radically different approach [Diffie-Hellman76, RSA78]
- ❑ sender, receiver do *not* share secret key
- ❑ *public* encryption key known to *all*
- ❑ *private* decryption key known only to receiver

Public key cryptography

Public key encryption algorithms

Requirements:

① need $K_B^+(\cdot)$ and $K_B^-(\cdot)$ such that

$$K_B^-(K_B^+(m)) = m$$

② given public key K_B^+ , it should be impossible to compute private key K_B^-

RSA: Rivest, Shamir, Adleman algorithm

RSA: another important property

The following property will be *very* useful later:

$$\underbrace{K_B^-(K_B^+(m))}_{\text{use public key first, followed by private key}} = m = \underbrace{K_B^+(K_B^-(m))}_{\text{use private key first, followed by public key}}$$

use public key
first, followed
by private key

use private key
first, followed
by public key

Result is the same!

Message Integrity

Bob receives msg from Alice, wants to ensure:

- ❑ message originally came from Alice
- ❑ message not changed since sent by Alice

Cryptographic Hash:

- ❑ takes input m , produces fixed length value, $H(m)$
 - e.g., as in Internet checksum
- ❑ computationally infeasible to find two different messages, x , y such that $H(x) = H(y)$
 - equivalently: given $m = H(x)$, (x unknown), can not determine x .
 - note: Internet checksum *fails* this requirement!

Internet checksum: poor crypto hash function

Internet checksum has some properties of hash function:

- ✓ produces fixed length digest (16-bit sum) of message
- ✓ is many-to-one

But given message with given hash value, it is easy to find another message with same hash value:

<u>message</u>	<u>ASCII format</u>
----------------	---------------------

I O U 1	49 4F 55 31
---------	-------------

0 0 . 9	30 30 2E 39
---------	-------------

9 B O B	39 42 4F 42
---------	-------------

B2 C1 D2 AC

<u>message</u>	<u>ASCII format</u>
----------------	---------------------

I O U <u>9</u>	49 4F 55 <u>39</u>
----------------	--------------------

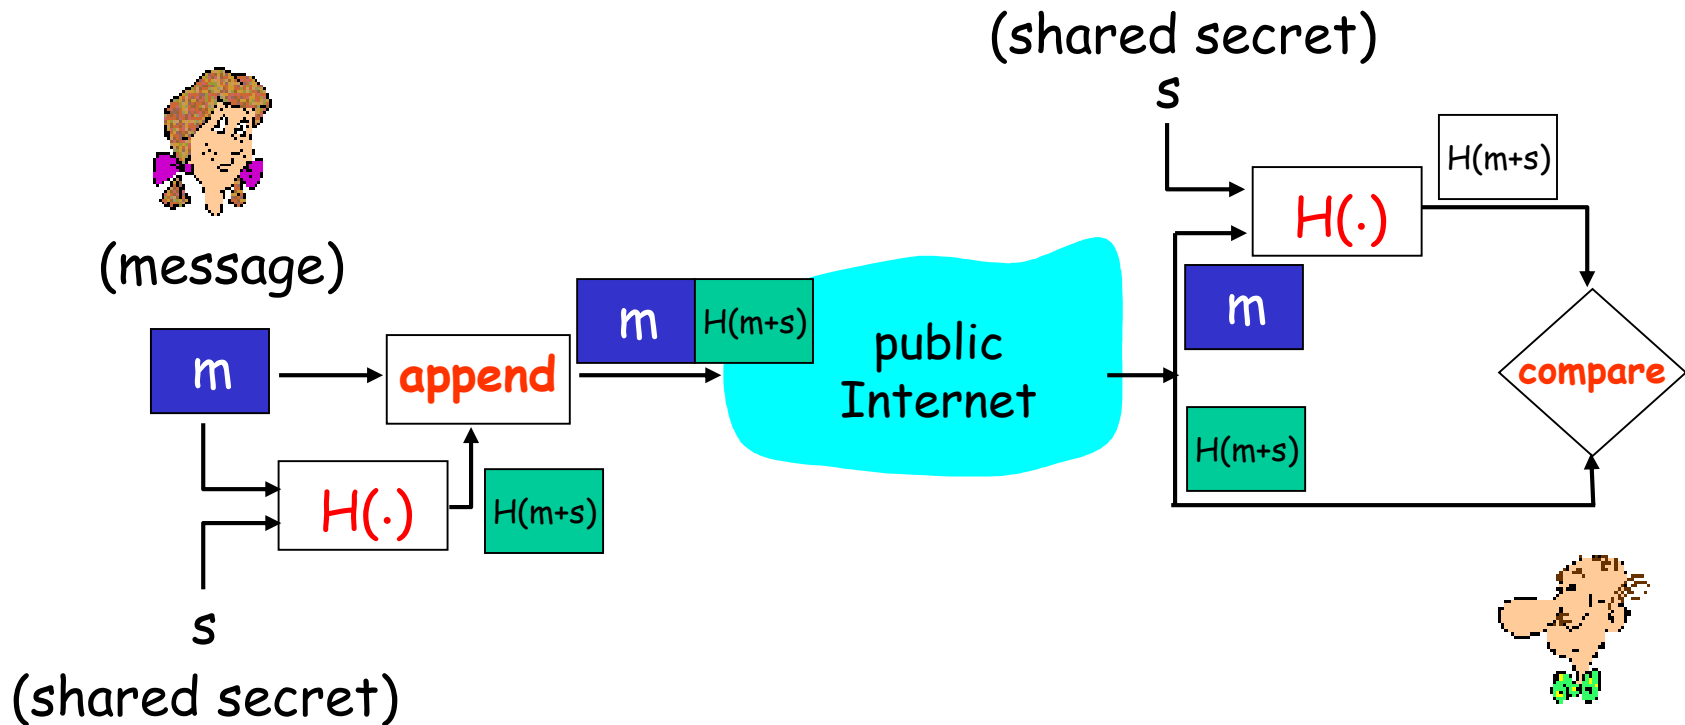

0 0 . <u>1</u>	30 30 2E <u>31</u>
----------------	--------------------

9 B O B	39 42 4F 42
---------	-------------

B2 C1 D2 AC

different messages
but identical checksums!

Message Authentication Code

MACs in practice

- MD5 hash function widely used (RFC 1321)
 - computes 128-bit MAC (Message Authentication Code) in 4-step process.
 - arbitrary 128-bit string x , appears difficult to construct msg m whose MD5 hash is equal to x

- SHA-1 is also used
 - US standard [NIST, FIPS PUB 180-1]
 - 160-bit MAC

Digital Signatures

cryptographic technique analogous to handwritten signatures.

- sender (Bob) digitally signs document, establishing he is document owner/creator.
- **verifiable, nonforgeable**: recipient (Alice) can prove to someone that Bob, and no one else (including Alice), must have signed document

Digital Signatures

simple digital signature for message m :

- Bob "signs" m by encrypting with his private key K_B^- , creating "signed" message, $K_B^-(m)$

Bob's message, m

Dear Alice
Oh, how I have missed
you. I think of you all the
time! ... (blah blah blah)
Bob

 K_B^- Bob's private
key

public key
encryption
algorithm

$K_B^-(m)$

Bob's message,
 m , signed
(encrypted) with
his private key

Digital Signatures (more)

- suppose Alice receives msg m , digital signature $K_B^-(m)$
- Alice verifies m signed by Bob by applying Bob's public key K_B^+ to $K_B^-(m)$ then checks $K_B^+(K_B^-(m)) = m$.
- if $K_B^+(K_B^-(m)) = m$, whoever signed m must have used Bob's private key.

Alice thus verifies that:

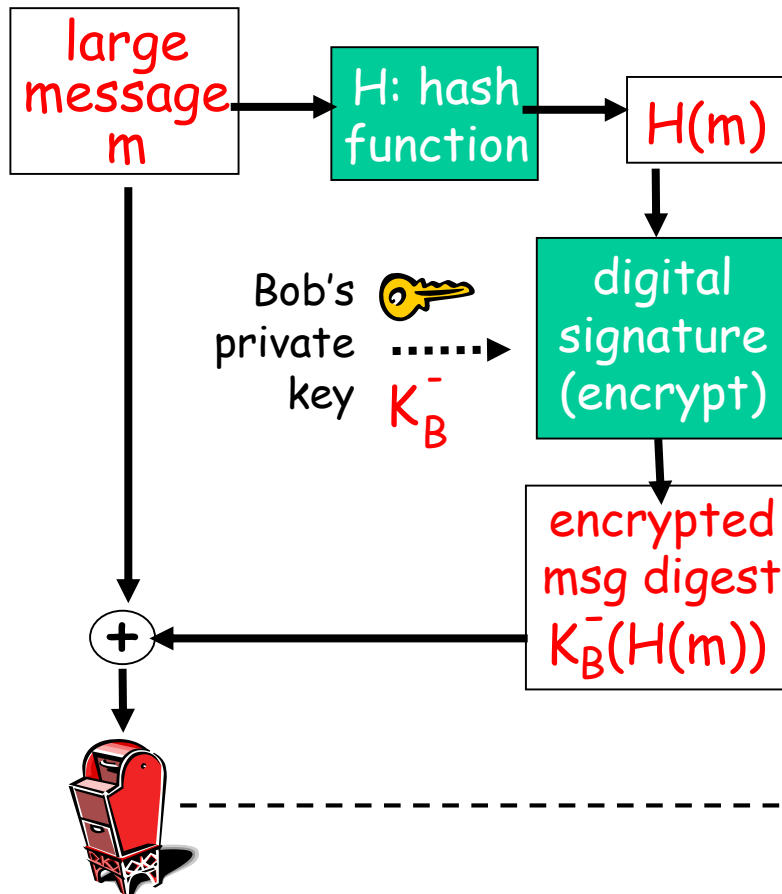

- ✓ Bob signed m .
- ✓ No one else signed m .
- ✓ Bob signed m and not m' .

non-repudiation:

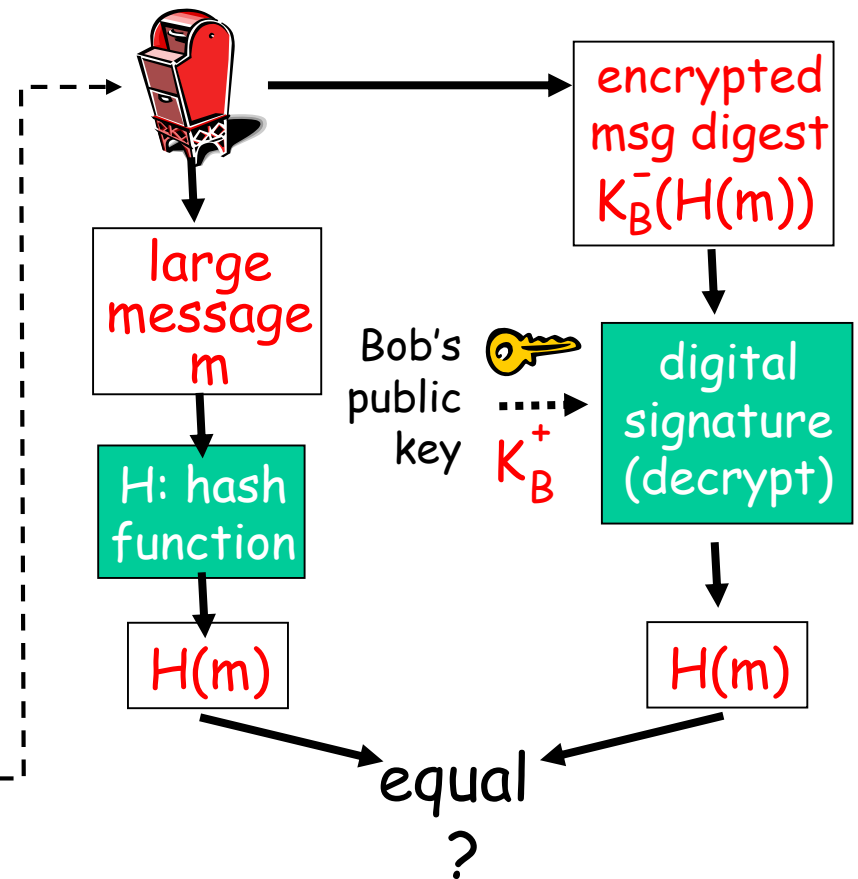

- ✓ Alice can take m , and signature $K_B^-(m)$ to court and prove that Bob signed m .

Digital signature = signed MAC

Bob sends digitally signed message:

Alice verifies signature and integrity of digitally signed message:

Public Key Certification

public key problem:

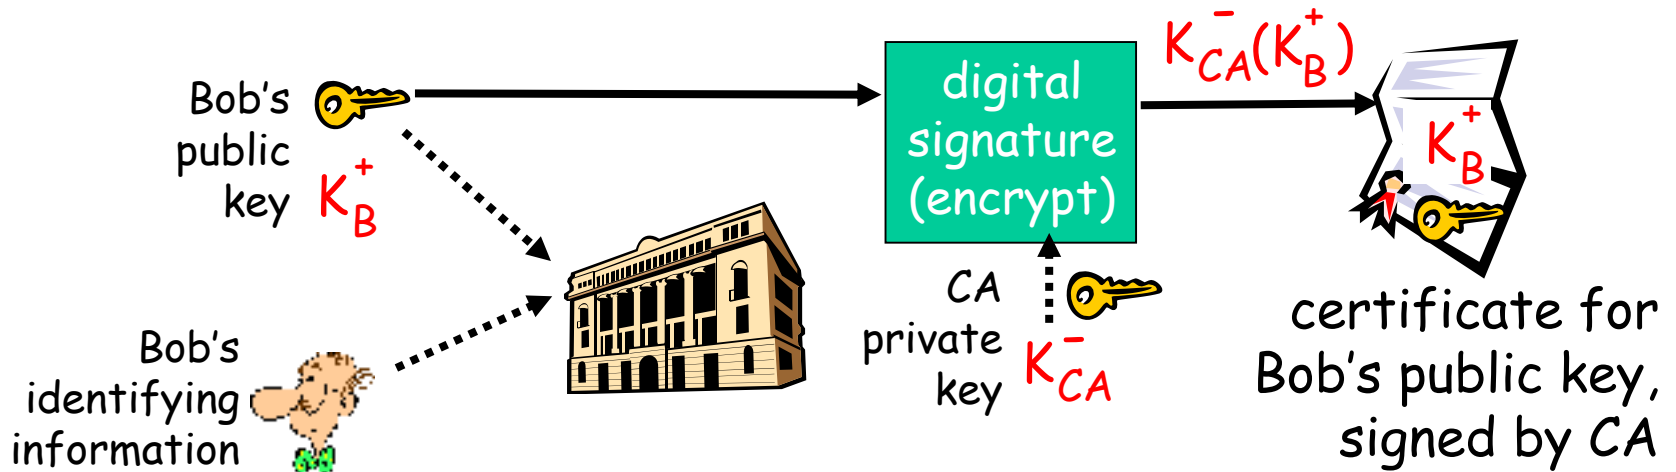

- When Alice obtains Bob's public key (from web site, e-mail, diskette), how does she *know* it is Bob's public key, not Trudy's?

solution:

- trusted certification authority (CA)

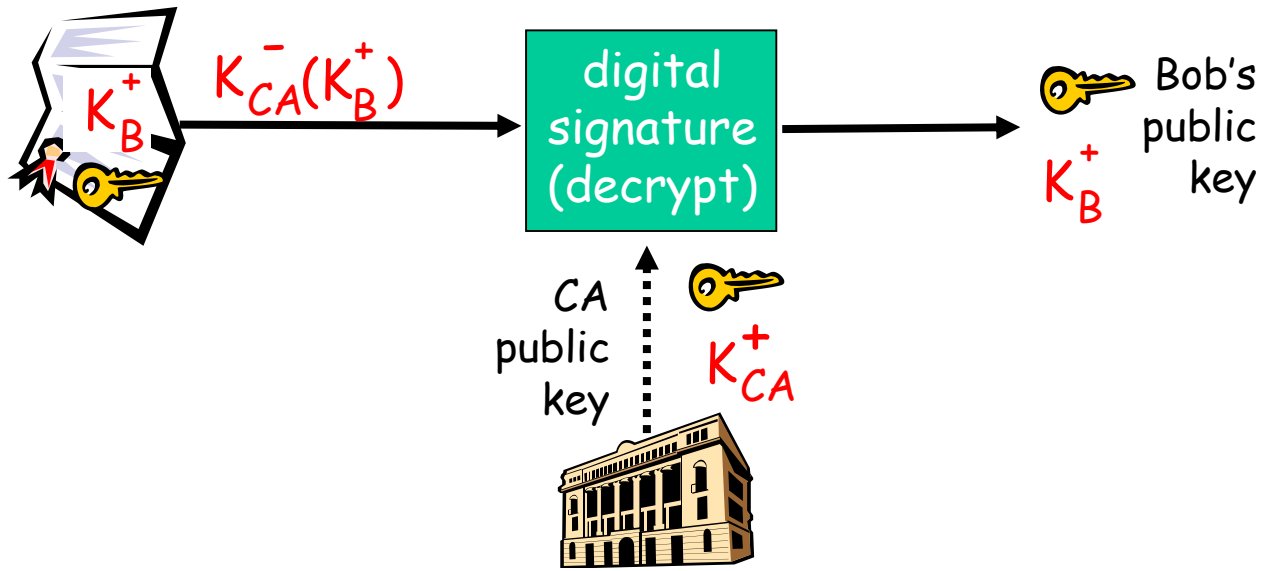

Certification Authorities

- ❑ **Certification Authority (CA):** binds public key to particular entity, E.
- ❑ E registers its public key with CA.
 - E provides "proof of identity" to CA.
 - CA creates certificate binding E to its public key.
 - certificate containing E's public key digitally signed by CA: CA says "This is E's public key."

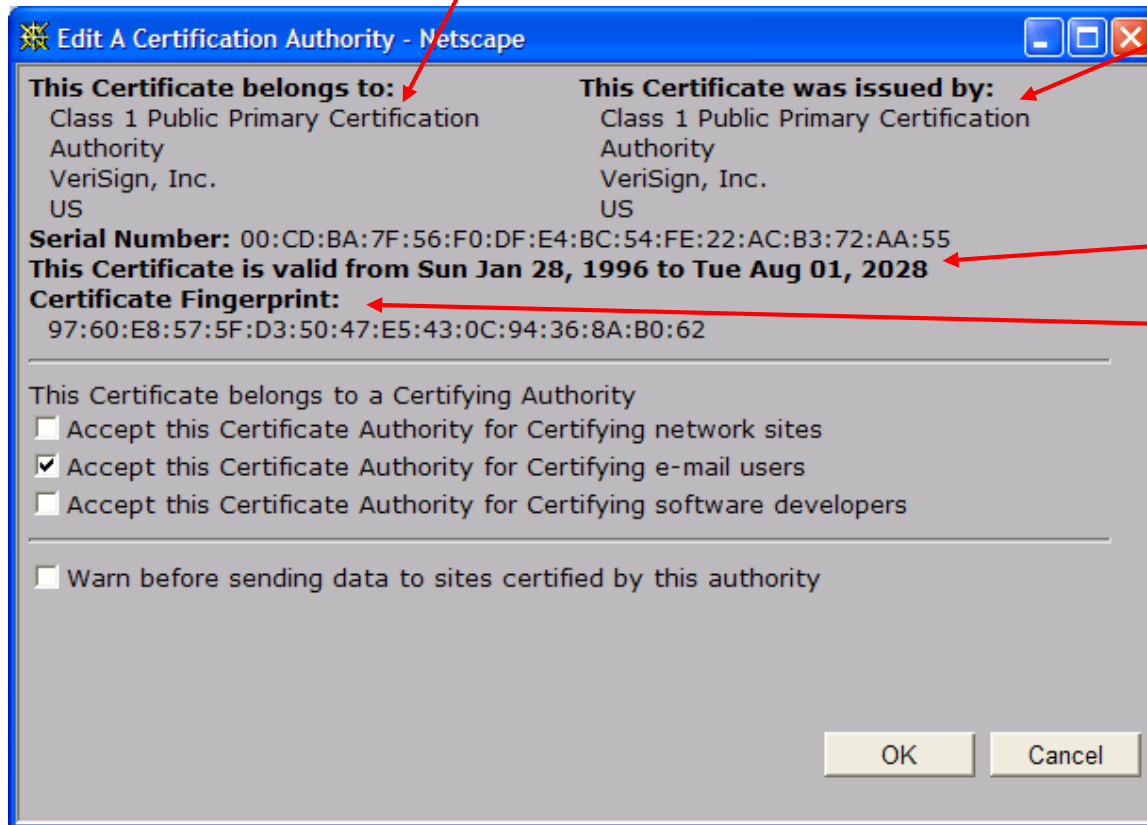

Certification Authorities

- when Alice wants Bob's public key:
 - gets Bob's certificate (Bob or elsewhere).
 - apply CA's public key to Bob's certificate, get Bob's public key

A certificate contains:

- ❑ Serial number (unique to issuer)
- ❑ info about certificate owner, including algorithm and key value itself (not shown)

- ❑ info about certificate issuer
- ❑ valid dates
- ❑ digital signature by issuer

Network Security (summary)

Basic techniques.....

- cryptography (symmetric and public)
- message integrity
- end-point authentication

.... used in many different security scenarios

- secure email
- secure transport (SSL)
- IP sec
- 802.11

Operational Security: firewalls and IDS

Secure e-mail

- Alice wants to send confidential e-mail, m , to Bob.

Alice:

- generates random *symmetric* private key, K_S .
- encrypts message with K_S (for efficiency)
- also encrypts K_S with Bob's public key.
- sends both $K_S(m)$ and $K_B(K_S)$ to Bob.

Secure e-mail

- Alice wants to send confidential e-mail, m , to Bob.

Bob:

- uses his private key to decrypt and recover K_S
- uses K_S to decrypt $K_S(m)$ to recover m

Secure e-mail (continued)

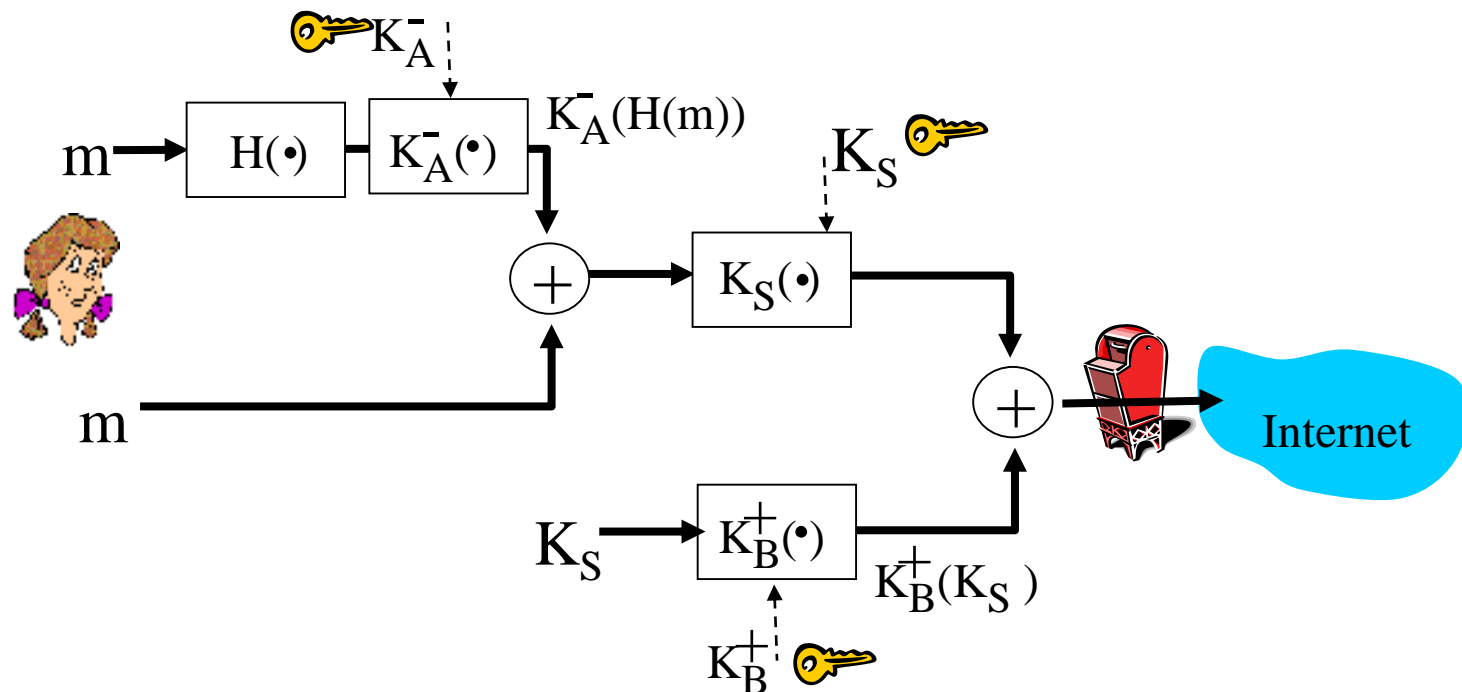

- Alice wants to provide sender authentication message integrity.

- Alice digitally signs message.
- sends both message (in the clear) and digital signature.

Secure e-mail (continued)

- Alice wants to provide secrecy, sender authentication, message integrity.

Alice uses three keys: her private key, Bob's public key, newly created symmetric key

Pretty good privacy (PGP)

- ❑ Internet e-mail encryption scheme, de-facto standard.
- ❑ uses symmetric key cryptography, public key cryptography, hash function, and digital signature as described.
- ❑ provides secrecy, sender authentication, integrity.
- ❑ inventor, Phil Zimmerman, was target of 3-year federal investigation.

A PGP signed message:

```
---BEGIN PGP SIGNED MESSAGE---  
Hash: SHA1  
  
Bob:My husband is out of town  
    tonight.Passionately yours,  
    Alice  
  
---BEGIN PGP SIGNATURE---  
Version: PGP 5.0  
Charset: noconv  
yhHJRHhGJGhgg/12EpJ+lo8gE4vB3mqJ  
    hFEvZP9t6n7G6m5Gw2  
---END PGP SIGNATURE---
```

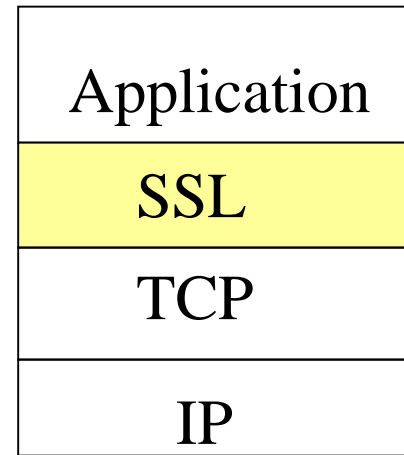

SSL: Secure Sockets Layer

- ❑ Widely deployed security protocol
 - Supported by almost all browsers and web servers
 - https
 - Tens of billions \$ spent per year over SSL
- ❑ Originally designed by Netscape in 1993
- ❑ Number of variations:
 - TLS: transport layer security, RFC 2246
- ❑ Provides
 - Confidentiality
 - Integrity
 - Authentication
- ❑ Original goals:
 - Had Web e-commerce transactions in mind
 - Encryption (especially credit-card numbers)
 - Web-server authentication
 - Optional client authentication
 - Minimum hassle in doing business with new merchant
- ❑ Available to all TCP applications
 - Secure socket interface

SSL and TCP/IP

Normal Application

Application
with SSL

- SSL provides application programming interface (API) to applications
 - C and Java SSL libraries/classes readily available

What is confidentiality at the network-layer?

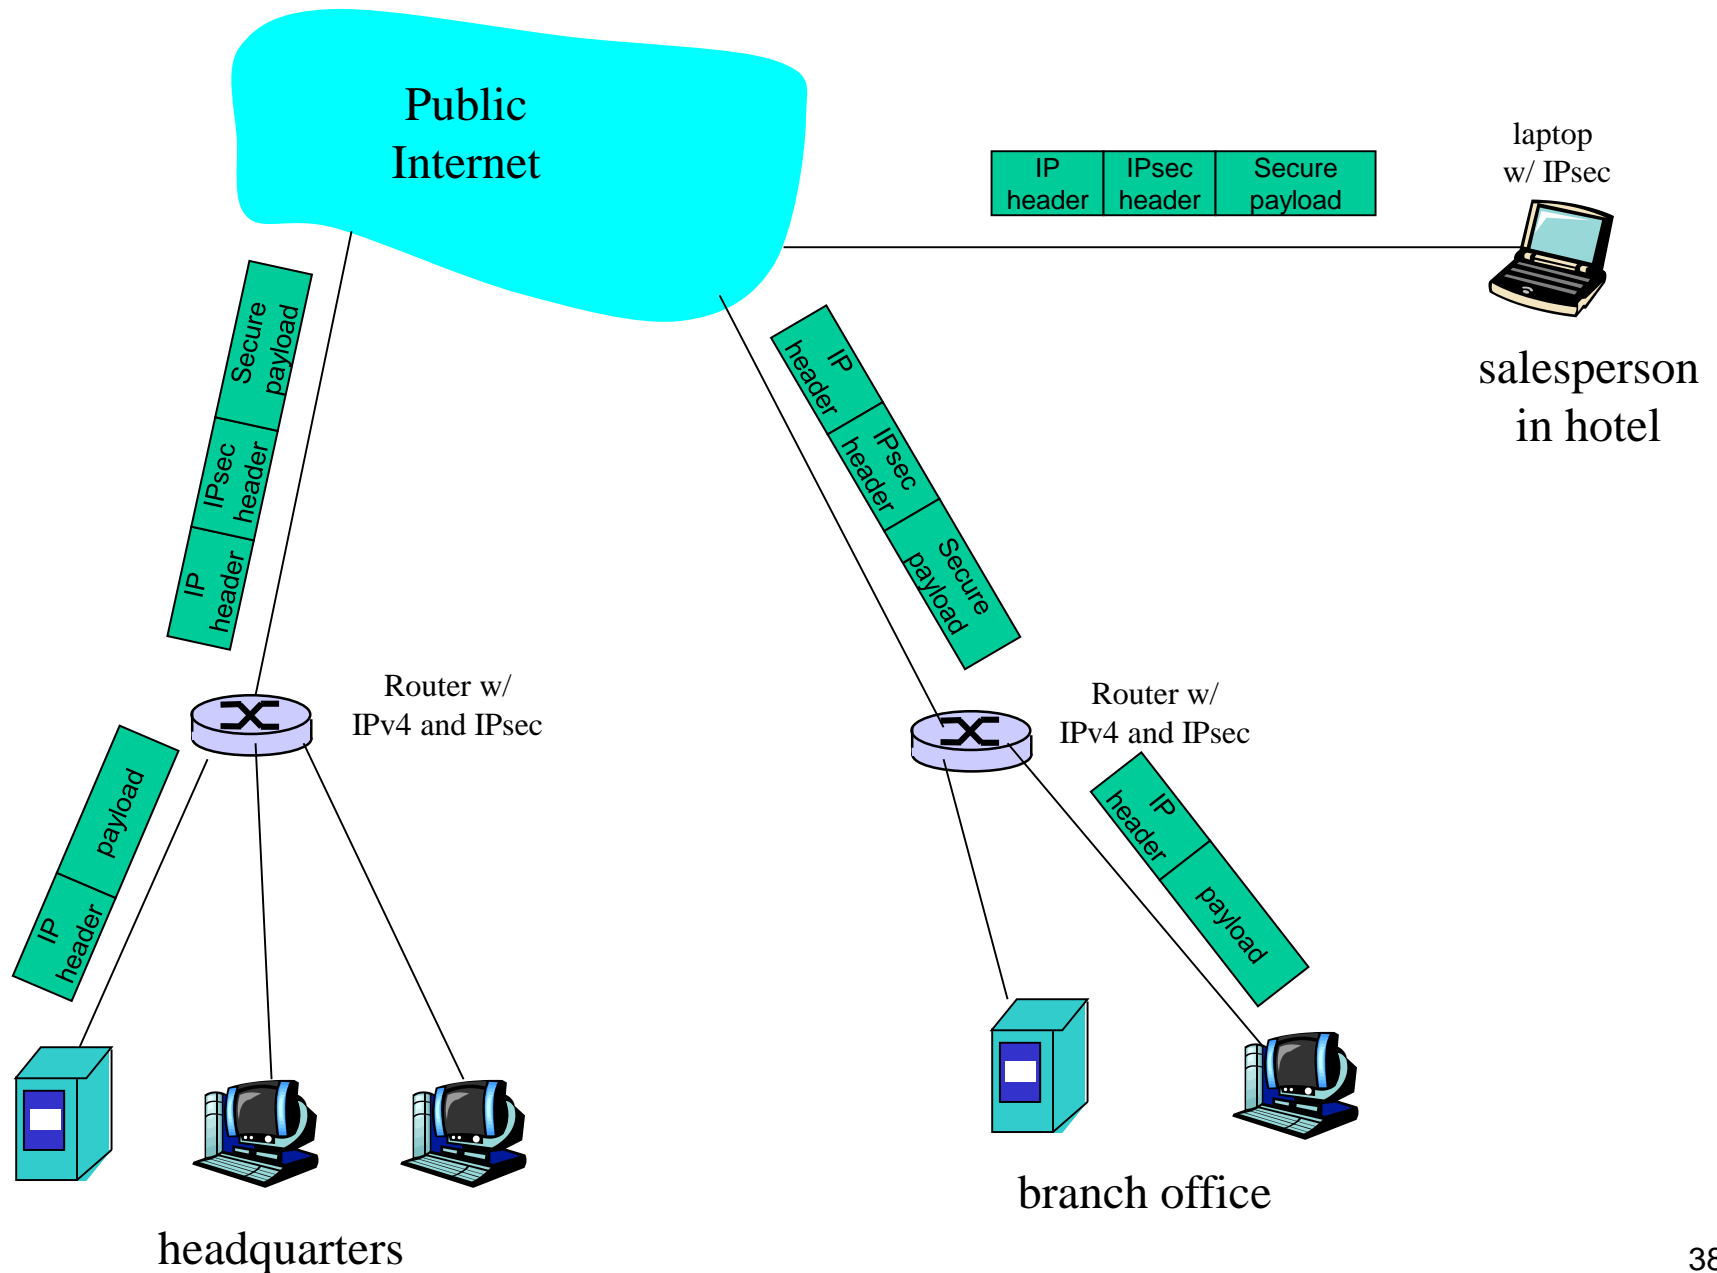

Between two network entities:

- ❑ Sending entity encrypts the payloads of datagrams. Payload could be:
 - TCP segment, UDP segment, ICMP message, OSPF message, and so on.
- ❑ All data sent from one entity to the other would be hidden:
 - Web pages, e-mail, P2P file transfers, TCP SYN packets, and so on.

Virtual Private Networks (VPNs)

- ❑ Institutions often want private networks for security.
 - Costly! Separate routers, links, DNS infrastructure.
- ❑ With a VPN, institution's inter-office traffic is sent over public Internet instead.
 - But inter-office traffic is encrypted before entering public Internet

Virtual Private Network (VPN)

IPsec services

- ❑ Data integrity
- ❑ Origin authentication
- ❑ Replay attack prevention
- ❑ Confidentiality

- ❑ Two protocols providing different service models:
 - AH
 - ESP

IPsec Transport Mode

- ❑ IPsec datagram emitted and received by end-system.
- ❑ Protects upper level protocols

IPsec - tunneling mode (1)

- End routers are IPsec aware. Hosts need not be.

IPsec - tunneling mode (2)

□ Also tunneling mode.

Two protocols

- ❑ Authentication Header (AH) protocol
 - provides source authentication & data integrity but *not* confidentiality
- ❑ Encapsulation Security Protocol (ESP)
 - provides source authentication, data integrity, *and confidentiality*
 - more widely used than AH

Security associations (SAs)

- ❑ Before sending data, a virtual connection is established from sending entity to receiving entity.
- ❑ Called "security association (SA)"
 - SAs are simplex: for only one direction
- ❑ Both sending and receiving entities maintain *state information* about the SA
 - Recall that TCP endpoints also maintain state information.
 - IP is connectionless; IPsec is connection-oriented!
- ❑ How many SAs in VPN w/ headquarters, branch office, and n traveling salesperson?

Example SA from R1 to R2

R1 stores for SA

- ❑ 32-bit identifier for SA: *Security Parameter Index (SPI)*
- ❑ the origin interface of the SA (200.168.1.100)
- ❑ destination interface of the SA (193.68.2.23)
- ❑ type of encryption to be used (for example, 3DES with CBC)
- ❑ encryption key
- ❑ type of integrity check (for example, HMAC with MD5)
- ❑ authentication key

Firewalls

firewall

isolates organization's internal net from larger Internet, allowing some packets to pass, blocking others.

Firewalls: Why

prevent denial of service attacks:

- SYN flooding: attacker establishes many bogus TCP connections, no resources left for “real” connections

prevent illegal modification/access of internal data.

- e.g., attacker replaces CIA's homepage with something else

allow only authorized access to inside network (set of authenticated users/hosts)

three types of firewalls:

- stateless packet filters
- stateful packet filters
- application gateways

Intrusion detection systems

❑ packet filtering:

- operates on TCP/IP headers only
- no correlation check among sessions

❑ *IDS: intrusion detection system*

- *deep packet inspection*: look at packet contents (e.g., check character strings in packet against database of known virus, attack strings)
- *examine correlation* among multiple packets
 - port scanning
 - network mapping
 - DoS attack
